

11.1 Set abstract data type

Set abstract data type

A **set** is a collection of distinct elements. A set **add** operation adds an element to the set, provided an equal element doesn't already exist in the set. A set is an unordered collection. Ex: The set with integers 3, 7, and 9 is equivalent to the set with integers 9, 3 and 7.

PARTICIPATION ACTIVITY

11.1.1: Set abstract data type.

Animation content:

undefined

Animation captions:

1. Adding 67, 91, and 14 produces a set with 3 elements.
2. Because 91 already exists in the set, adding 91 any number of additional times has no effect.
3. Set 2 is built by adding the same numbers in a different order.
4. Because order does not matter in a set, the 2 sets are equivalent.

PARTICIPATION ACTIVITY

11.1.2: Set abstract data type.

1) Which of the following is not a valid set?

- ☐ { 78, 32, 46, 57, 82 }
- ☐ { 34, 8, 92 }
- ☐ { 78, 28, 91, 28, 15 }

2) How many elements are in a set that is built by adding the element 28 6 times, then the element 54 9 times?

- ☐ 1
- ☐ 2
- ☐ 15

3) Which 2 sets are equivalent?

- ☒ { 56, 19, 71 } and { 19, 65, 71, 56 }
- ☐ { 88, 54, 81 } and { 81, 88, 54 }
- ☐ { 39, 56, 14, 11 } and { 14, 56, 93, 11 }

©zyBooks 04/04/22 19:24 1093648

Element keys and removal

Set elements may be primitive data values, such as numbers or strings, or objects with numerous data members. When storing objects, set implementations commonly distinguish elements based on an element's **key value**: A primitive data value that serves as a unique identifier for the element. Ex: An object for a student at a university may store information such as name, phone number, and ID number. No two students will have the same ID number, so the ID number can be used as the student object's key.

Sets are commonly implemented to use keys for all element types. When storing objects, the set retrieves an object's key via an external function or predetermined knowledge of which object property is the key value. When storing primitive data values, each primitive data value's key is itself.

Given a key, a set **remove** operation removes the element with the specified key from the set.

PARTICIPATION ACTIVITY

11.1.3: Element keys and removal.

Animation content:

undefined

Animation captions:

1. Different students at the same university may have the same name or phone number, but each student has a unique ID number.
2. A set for the course roster uses the student ID as the key value, since the exact same student cannot enroll twice in the same course.
3. The call to remove Student C provides only the student ID.

BCCPS101LuSpring2022

Searching and subsets

Given a key, a set **search** operation returns the set element with the specified key, or null if no such element exists. The search operation can be used to implement a subset test. A set X is a **subset** of set Y only if every element of X is also an element of Y.

PARTICIPATION ACTIVITY

11.1.5: SetIsSubset algorithm.

Animation content:

undefined

Animation captions:

1. To test if set2 is a subset of set1, each element of set 2 is searched for in set1. Elements 19, 22, and 26 are found in set1.
2. Element 34 is in set2 but not set1, so set2 is not a subset of set1.
3. The first element in set3, 88, is not in set1, so set3 is not a subset of set1.
4. All elements of set4 are in set1, so set4 is a subset of set1.
5. No other set is a subset of another.
6. But each set is always a subset of itself.

Next

11.2 Set operations

Union, intersection, and difference

The **union** of sets X and Y , denoted as $X \cup Y$, is a set that contains every element from X , every element from Y , and no additional elements. Ex: $\{54, 19, 75\} \cup \{75, 12\} = \{12, 19, 54, 75\}$.

The **intersection** of sets X and Y , denoted as $X \cap Y$, is a set that contains every element that is in both X and Y , and no additional elements. Ex: $\{54, 19, 75\} \cap \{75, 12\} = \{75\}$.

The **difference** of sets X and Y , denoted as $X \setminus Y$, is a set that contains every element that is in X but not in Y , and no additional elements. Ex: $\{54, 19, 75\} \setminus \{75, 12\} = \{54, 19\}$.

The union and intersection operations are commutative, so $X \cup Y = Y \cup X$ and $X \cap Y = Y \cap X$. The difference operation is not commutative.

PARTICIPATION ACTIVITY

11.2.1: Set union, intersection, and difference.

Animation content:

undefined

Animation captions:

1. The union operation begins by adding all elements from set1.
2. Each element from set2 is added. Adding elements 82 and 93 has no effect, since 82 and 93 already exist in the result set.
3. The intersection operation iterates through each element in set1. Each element that is also in set2 is added to the result.
4. The difference of set1 and set2, denoted $\text{set1} \setminus \text{set2}$, iterates through all elements in set1. Only elements 61 and 76 are added to the result, since these elements are not in set2.
5. Set difference is not commutative. $\text{SetDifference}(\text{set2}, \text{set1})$ produces a result containing only 23 and 46, since those elements are in set2 but not in set1.

PARTICIPATION ACTIVITY

Filter and map

A **filter** operation on set X produces a subset containing only elements from X that satisfy a particular condition. The condition for filtering is commonly represented by a **filter predicate**: A function that

takes an element as an argument and returns a Boolean value indicating whether or not that element will be in the filtered subset.

A **map** operation on set X produces a new set by applying some function F to each element. Ex: If $X = \{18, 44, 38, 6\}$ and F is a function that divides a value by 2, then $\text{SetMap}(X, F) = \{9, 22, 19, 3\}$.

11.3 Static and dynamic set operations

A **dynamic set** is a set that can change after being constructed. A **static set** is a set that doesn't change after being constructed. A collection of elements is commonly provided during construction of a static set, each of which is added to the set. Ex: A static set constructed from the list of integers (19, 67, 77, 67, 59, 19) would be { 19, 67, 77, 59 }.

Static sets support most set operations by returning a new set representing the operation's result. The table below summarizes the common operations for static and dynamic sets.

Shayan McNeilly
BCCPS101LuSpring2022

Implementing a set with a binary search tree

A set can be implemented in Java using a binary search tree (BST). In practice, a balanced BST or hash table is often used to efficiently implement a set, but a BST will suffice for all necessary set operations.

This section implements a set of integers for simplicity. In practice, a set class is commonly generic, allowing data types other than integers.

The BSTNode class represents a node in a binary search tree. Each node's data stores a set element. References to left child, right child, and parent nodes are also included. The count(), getSuccessor(), and replaceChild() methods assist with implementation of the BST.

Figure 11.4.1: BSTNode class definition.

©zyBooks 04/04/22 19:24 1093648
Shayan McNeilly
BCCPS101LuSpring2022

```
class BSTNode {
    public int data;
    public BSTNode parent;
    public BSTNode left;
    public BSTNode right;

    public BSTNode(int data, BSTNode parent, BSTNode left, BSTNode right) {
        this.data = data;
        this.parent = parent;
        this.left = left;
        this.right = right;
    }

    public BSTNode(int data, BSTNode parent) {
        this(data, parent, null, null);
    }

    public int count() {
        int leftCount = 0;
        int rightCount = 0;
        if (left != null) {
            leftCount = left.count();
        }
        if (right != null) {
            rightCount = right.count();
        }
        return 1 + leftCount + rightCount;
    }

    public BSTNode getSuccessor() {
        // Successor resides in right subtree, if present
        if (right != null) {
            BSTNode successor = right;
            while (successor.left != null) {
                successor = successor.left;
            }
            return successor;
        }

        // Otherwise the successor is up the tree
        // Traverse up the tree until a parent is encountered from the left
        BSTNode node = this;
        while (node.parent != null && node == node.parent.right) {
            node = node.parent;
        }

BSTIterator class

The set implementation supports iterating through all items in the set. The Set class's iterator() method constructs and returns a BSTIterator object referencing the minimum node in the tree. The BSTIterator class implements an iterator that stores a reference to a node in the BST and supports moving to the successor node when the next() method is called.

Figure 11.4.2: BSTIterator class definition.

```
class BSTIterator implements Iterator<Integer> {
    private BSTNode nextNode;

    public BSTIterator(BSTNode startNode) {
        nextNode = startNode;
    }

    public boolean hasNext() {
        return nextNode != null;
    }

    public Integer next() {
        Integer returnMe = null;
        if (nextNode != null) {
            returnMe = nextNode.data;
            nextNode = nextNode.getSuccessor();
        }
        return returnMe;
    }
}

Set class: BST methods

The Set class implements standard BST functionality in the add(), remove(), and nodeSearch() methods. The contains() method uses nodeSearch() and returns true if an element is in the set, false if the element is not in the set. The size() method returns the number of elements in the set by counting the number of nodes in the BST.

Figure 11.4.3: Set class methods for implementing a BST.

```
class Set implements Iterable<Integer> {
    private BSTNode root;

    public Set() {
        root = null;
    }

    public boolean add(Integer newElement) {
        if (contains(newElement)) {
            return false;
        }

        BSTNode newNode = new BSTNode(newElement, null);

        // Special case for empty set
        if (root == null) {
            root = newNode;
            return true;
        }

        BSTNode node = root;
        while (node != null) {
            if (newElement < node.data) {
                // Go left
                if (node.left != null) {
                    node = node.left;
                }
            }
            else {
                node.left = newNode;
                newNode.parent = node;
                node = null;
            }
        }
        else {

PARTICIPATION ACTIVITY

11.4.3: Set class: BST methods.

- 1) The size() method returns ____
 when the root is null.

Check

Show answer

- 2) The `remove()` method calls both the `removeNode()` and ____ methods.

Check[Show answer](#)

©zyBooks 04/04/22 19:24 1093648
Shayan McNeilly
BCCPS101LuSpring2022

- 3) The `add()` method first calls the ____ method to see if the element already exists in the set.

Check[Show answer](#)

- 4) The ____ method returns an iterator that allows iteration through the Set's elements using an enhanced for loop.

Check[Show answer](#)

Set class: methods for set operations

The remaining methods in the Set class implement common set operations: `difference()`, `filter()`, `intersection()`, `map()`, and `union()`.

Figure 11.4.4: `difference()`, `filter()`, `intersection()`, `map()`, and `union()` methods.

Builds a new set by adding elements returned from a Function object's apply() method. apply() is called for each element in the instance set.

Builds and returns the set of elements that exist only in both sets.

Builds and returns the set of elements that exist in 1 or both sets.

Builds and returns the set of elements that exist only in the instance set, and not in the other set.

Builds and returns the set of elements from the instance set that satisfy the predicate.

Reset

zyDE 11.4.1: Java: Set implementation.

Definitions for the Set class are included in the Set.java file. Try changing the set element declarations on the first two lines in main() and see if you can calculate the result before running the code.
